

Distant Galaxy Clusters Uncovered by Herschel & Planck

David L Clements, Filiberto Braglia, Ashley Hyde
Imperial College London
The HerMES & H-ATLAS Collaborations

Planck and High Redshift Clusters

350 μm Sky: Planck & Herschel

- Simulation by Gonzales-Nuevo of 1 sq deg region including protocluster (top left) motivated by Granato et al (2004) dusty protocluster models.

Planck & Herschel Surveys

- Negrello et al. 2005 predict 100 - 10000 clumps per steradian detectable by Planck and Herschel
- Would detect appreciable numbers of these objects in HerMES (110 + 270 sq. deg.) and H-ATLAS (570 sq. deg.) surveys
- Working with 'followup' data to ERCSC that already exists

Fluxes and densities
accessible to Herschel Key
Programme Surveys

Planck ERCSC Sources in HerMES

- Expect three classes of sources to be detected by Planck in these fields:
 - Bright nearby galaxies
 - Appear as bright sources in HerMES
 - High latitude cirrus
 - Appear as extended diffuse emission in HerMES
 - Candidate protocluster ‘clumps’
 - Appear as overdensities of less bright sources

Example Planck Sources

250 micron images of HerMES Planck Sources

Example Planck Sources

250 micron images of HerMES Planck Sources

Results Summary

- For 4 well studied HerMES fields (XMM-LSS, Bootes, Lockman-SWIRE, CDFS-SWIRE) find:
 - 16 Planck Sources
 - 12 foreground sources (galaxies + Mira)
 - 4 clumps in ~ 90 sq. deg. \Rightarrow 1 per 22.5 sq. deg.
 - Not all HerMES fields yet included
 - No cirrus sources in this list

HerMES Catalog Overdensities

Smoothed, flux weighted catalog overdensity image
3 colour: B=250micron G=350micron R=500micron

Herschel & Planck Analysis

- Sources are overdensities of dusty galaxies
- Colours in Herschel and Planck suggest high redshift ($z > \sim 1$)
- Exactly what would be expected for the proposed dusty protoclusters

Followup

- Plentiful ancillary data exist for the CDFS and Bootes clumps
- Near IR J & K imaging for the EGS and Lockman clumps were obtained at TNG
- Allows us to look for evidence of cluster in CMD or in photo-z distribution

Results: Red Sequences

EGS: $z \sim 0.8$

Lockman: $z \sim 2.0$

Black = field, red = in Planck beam

Photo-z

CDFS: $z \sim 1.1$

Bootes: $z \sim 2.3$

Cluster Ages

- Can use results on these high z starforming clusters to examine aspects of cluster evolution

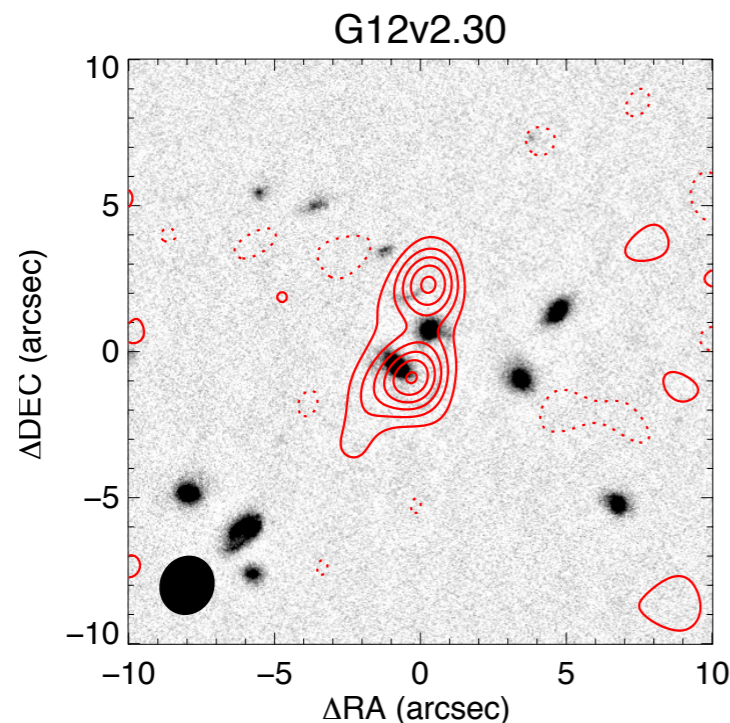

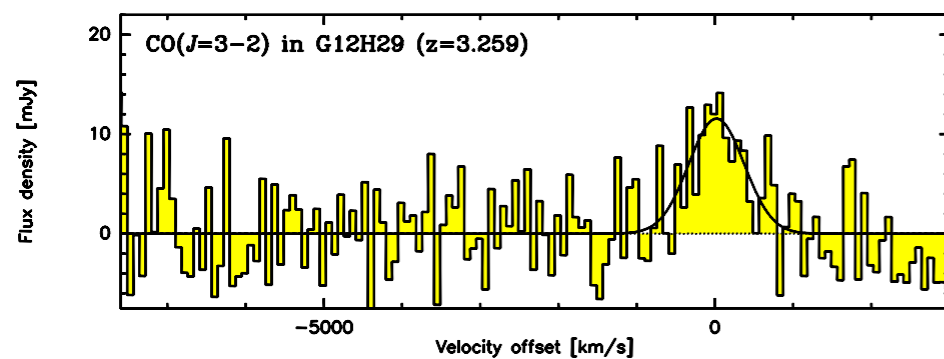

Colour vs redshift for 2 clumps & ISCS clusters compared to 4 different current ages

Clements et al. in press; Braglia et al. in prep

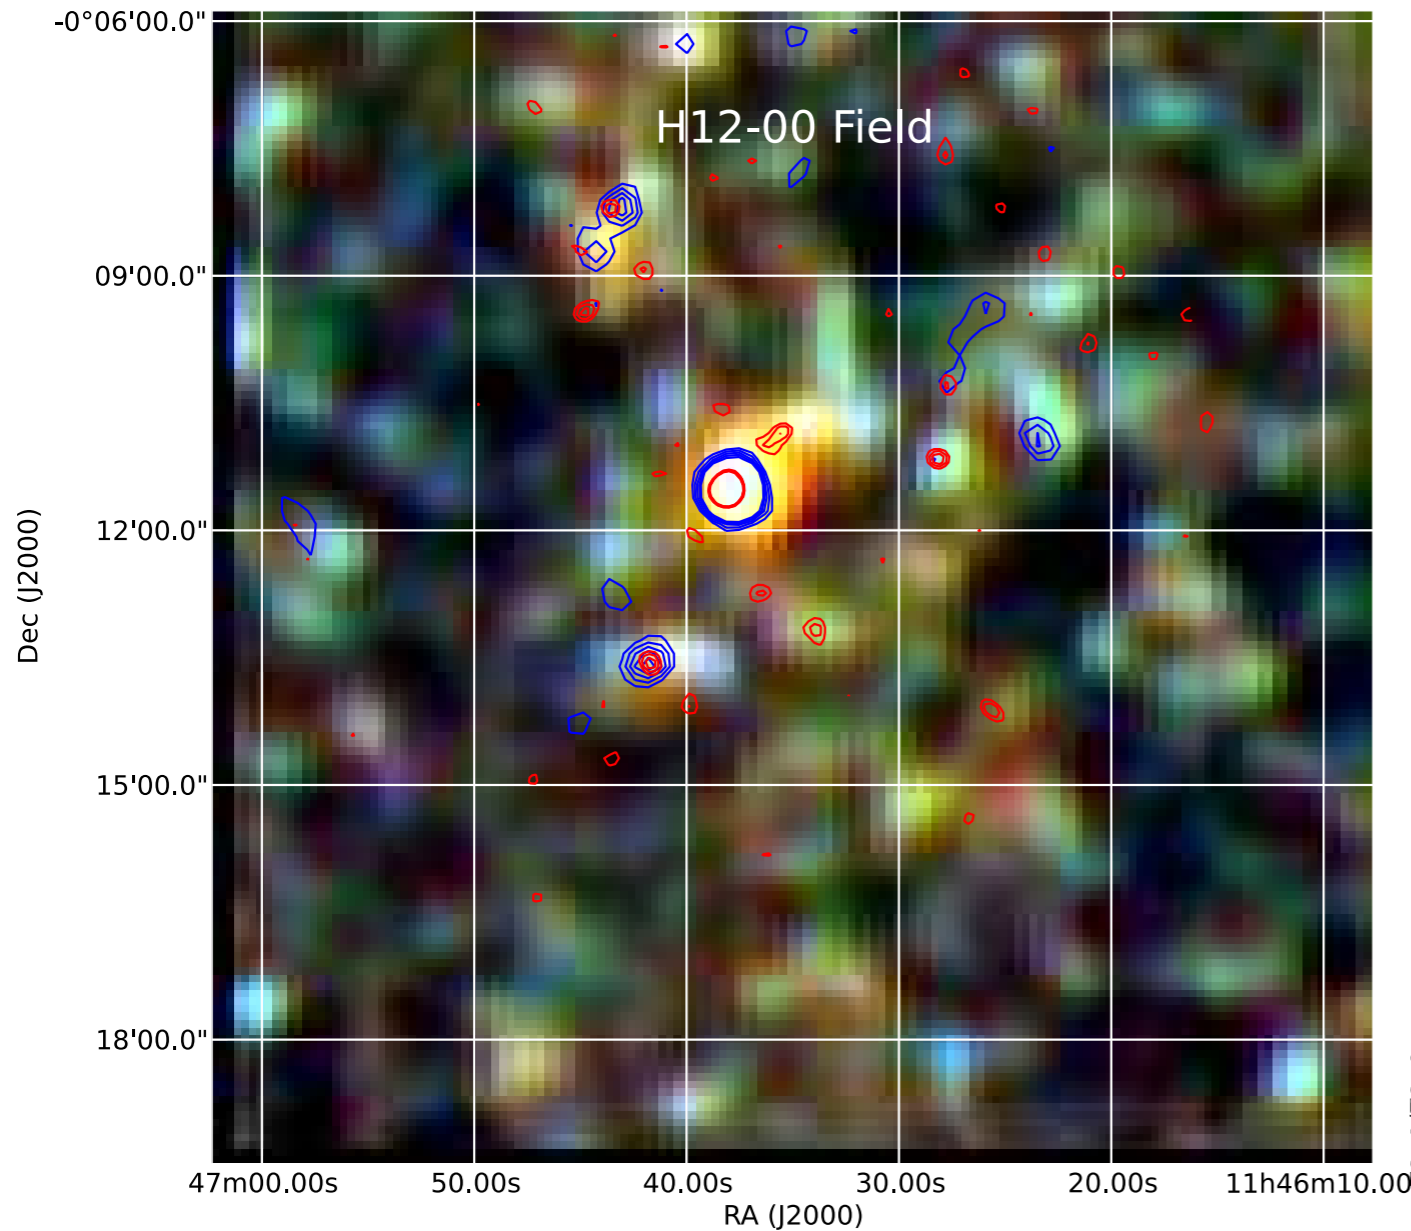

H-ATLAS Clumps

- Herranz et al. 2012 identify 1 clump in H-ATLAS GAMA fields
- Associated with $z=3.26$ lensed galaxy G12H29 in Fu et al. 2012

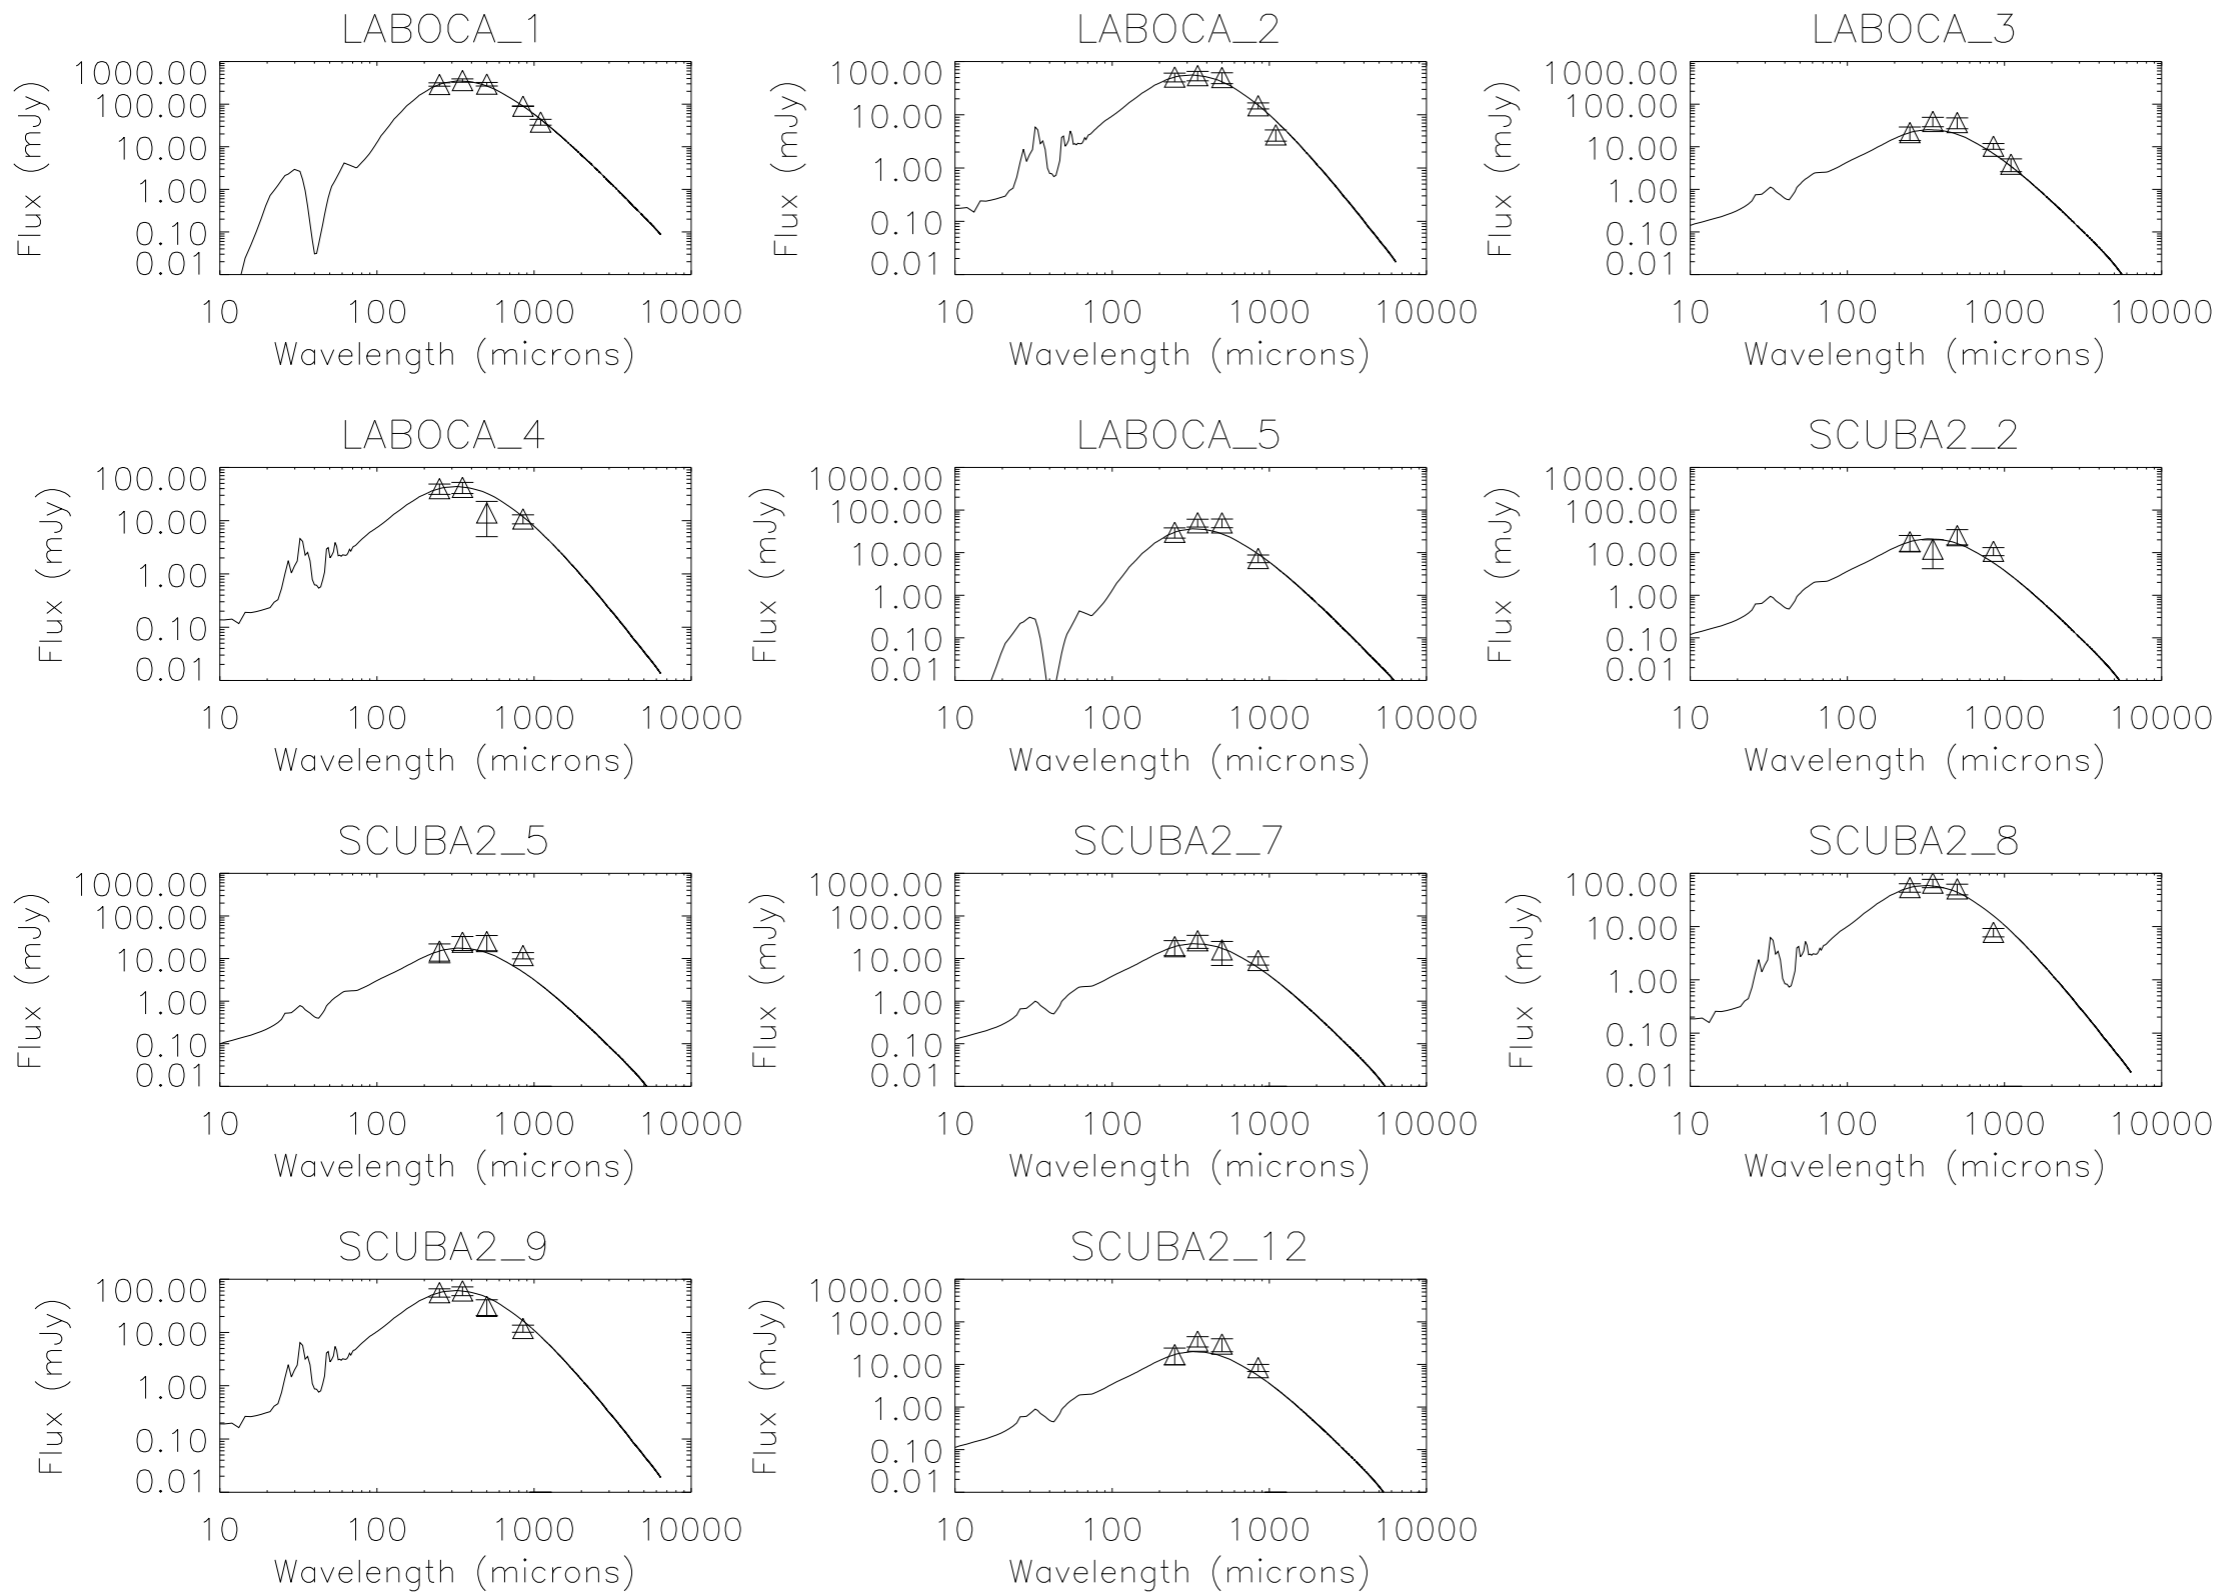

Is the clump at $z=3.26$?

- Submm observations provide extra fluxes for sources around G12H29

Herschel & Submm colours suggest Submm detections at similar z to lens

**Submm photo-z fits all consistent with I I companions
lying at same z as lensed source: $z=3.26$**

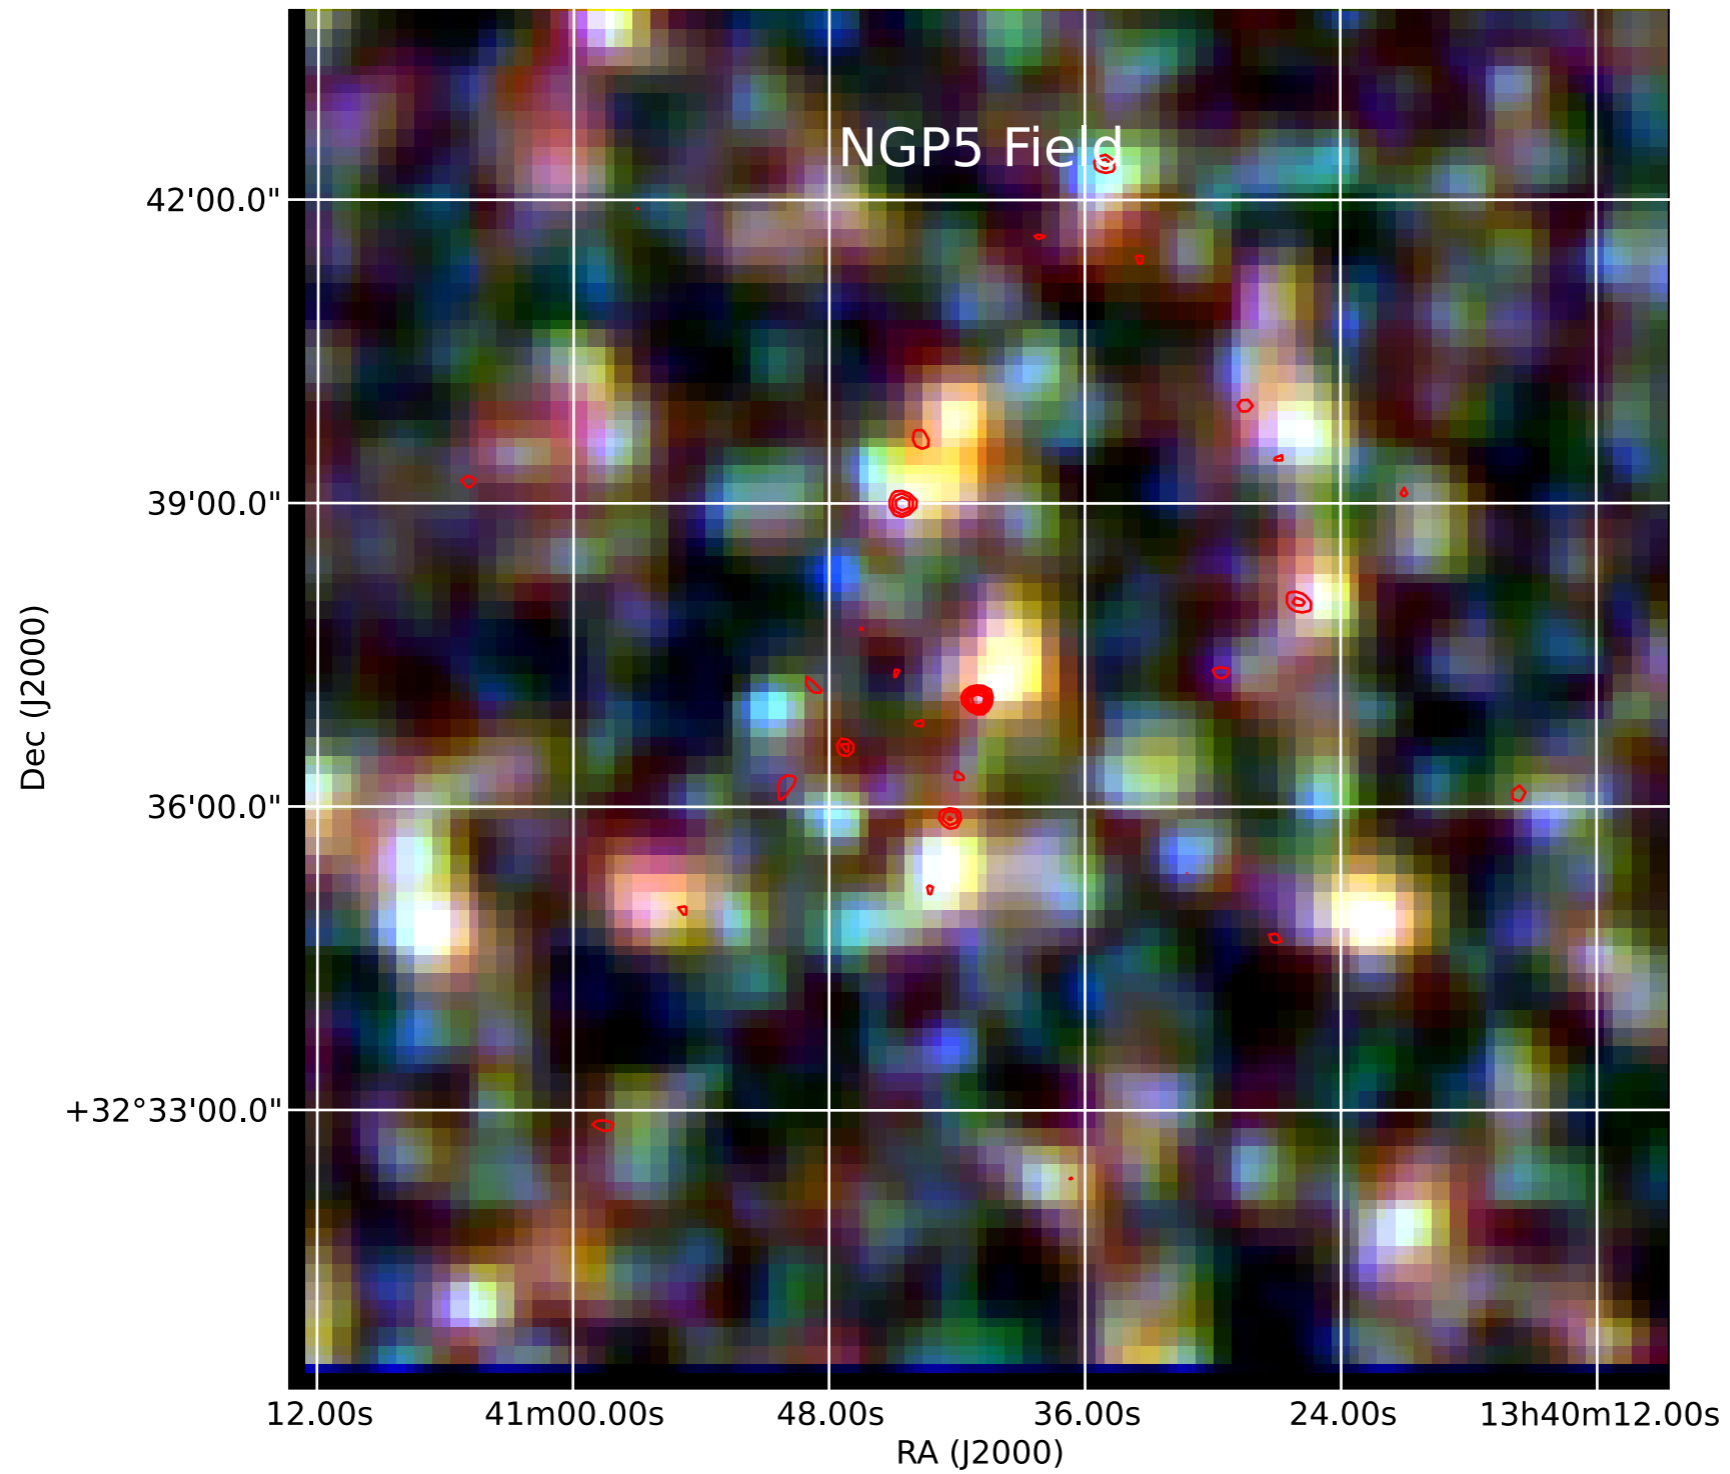

The SFRD of Clusters

- Compare with field SFR density evolution again
- Evolution from high z to $z \sim 1.2$ match, but cluster SFRD drops at lower z
- What happens at higher z ?

Field SSFR from Hopkins et al. 2006 (blue) and Bouwens et al. 2011 (orange)

More to Come!

Conclusions

- Combining Planck & Herschel allows the discovery of 'clumps' of dusty galaxies
- Appear to be high z clusters with many members going through simultaneous starbursts, some involve lensing
- Clusters found in this way at higher z than conventional searches allow
